

APPLICATION SUMMARY

Supersonic Wind Tunnels enable the observation of high-speed aerodynamics in a laboratory setting. As air moves through the tunnel, it is accelerated by a nozzle to supersonic velocities. The air moves over the specimen in the test section, generating shock waves as the air slows down to transonic speeds. All of this happens in a matter of microseconds and requires high-speed sensors to log pressure in the tunnel's throat and at various points along the model. To accomplish this, miniature flush mount pressure sensors are embedded throughout the wind tunnel.

PRODUCTS IN USE

Five PFT510 Flush Mount Diaphragm Pressure Sensors paired with Instrumentation (IAA Series or USB220)
